1. Photosynthesis converts light energy into chemical energy stored in glucose. In the light-dependent reactions, water is split and oxygen is released, while ATP and NADPH are produced. The Calvin cycle then uses these to fix carbon dioxide into sugars. Factors such as light intensity, temperature and CO2 concentration limit the overall rate.

2. Photosynthesis converts light energy into chemical energy stored in glucose. In the light-dependent reactions, water is split and oxygen is released, while ATP and NADPH are produced.
